

Interventional Stroke Management

DR. JAMES MCEACHERN

Faculty Disclosure

- ▶ No conflicts of interest or disclosures

Case 1: 65y male with acute onset right sided weakness and global aphasia ~2.5h ago. Initial imaging with CT and CTA; no acute hemorrhage or established infarct. Large vessel occlusion of the left M1 segment.

Case 2: 99y lady with acute onset right sided weakness and aphasia. Last known normal 1.5h, lives independently with a baseline modified Rankin score of 1. NIHSS of 20. History of a remote left MCA infarct.

Case 3: ~50y F with acute onset LOC, found down. Recovered to baseline by time of arrival to hospital and has been stable since symptom onset ~6h ago. Now has having multiple cranial nerve symptoms with a relatively mild neurological deficit.

Outline

- ▶ Overview of Interventional stroke treatment
 - ▶ Treatment strategies
 - ▶ Technical Aspects
 - ▶ Evidence
 - ▶ Patient Selection
 - ▶ Case examples

Treatment Strategies

- ▶ Intra arterial tPA
- ▶ Mechanical Thrombectomy
 - ▶ Stent-retrievers
 - ▶ Aspiration

Intra-arterial Thrombolytics

- ▶ Administering thrombolytic drugs (tPA) through a small catheter placed proximal to an occluded vessel
- ▶ Series of trials in the late 90's
 - ▶ Impressive recanalization rates
 - ▶ High rates of intracranial hemorrhage (~10%)

Mechanical Thrombectomy

- ▶ Removal of a large vessel occlusion through an angiographic approach
- ▶ Arterial access obtained, usually from the common femoral artery
- ▶ Series of catheters constructed, sequentially smaller
 - ▶ Larger catheters positioned within the neck
 - ▶ Smaller catheters advanced intracranially to remove the clot
- ▶ Stent retriever and Aspiration systems

Stent Retriever Systems

STENTRIEVER (early 2012)

3RD GENERATION

Engage the thrombus with stent retrieve deployment, which also temporarily restores flow across the occlusion. Proximal balloon inflation allows device retrieval into the guide while minimizing the risk of emboli.

STEPS

- Check clinical status
- Don't wait for lines , complete draping
- Local anesthesia.- anesthetist in lab – sedation
- If restless , consider GA
- But should be done without delay , avoiding drop in BP
- If IV tPA – single wall puncture, micropuncture set (closure device)
- 8 F short sheath
- 3000-5000 U heparin (not if tPA)

Aspiration Systems

2012

2013

Evidence

- ▶ Early experience with thrombectomy
 - ▶ Anecdotal positive outcomes
 - ▶ Limited experience, was a new procedure
- ▶ No large trials to prove it could work

Evidence

- ▶ 2013 three large trials published studying the interventional management of stroke
- ▶ All three failed to show a benefit
- ▶ Study design and technological limitations
 - ▶ Limited availability of CTA
 - ▶ Older thrombectomy devices
 - ▶ Treatment delays
 - ▶ Patient selection

Evidence

- ▶ 2015
 - ▶ 4 Large trials published documenting a clear cut efficacy
 - ▶ Varied design, patient selection, etc; however,
 - ▶ All included some form of advanced imaging (minimum CTA)
 - ▶ Patient selection
 - ▶ Advanced devices
 - ▶ Emphasized time and efficiency
 - ▶ Additional trials subsequently published further supporting mechanical thrombectomy.

Evidence

- ▶ Trials established that mechanical thrombectomy
 - ▶ Improves clinical outcomes
 - ▶ Significant increase in patients living independently
 - ▶ Trend towards decreased mortality
 - ▶ Is safe
 - ▶ Low complication rates
 - ▶ Overall better outcomes
 - ▶ Similar rates of intracranial hemorrhage
 - ▶ Is cost effective
 - ▶ High up front cost
 - ▶ Less time in hospital acutely
 - ▶ Less time in advanced care/assisted living facilities

Patient Selection

- ▶ Different trials utilized different selection criteria
- ▶ Individual hospitals attempt to standardize workflows taking into account their own resources, geography and experience
- ▶ General selection criteria include
 - ▶ Time since last known normal
 - ▶ Age
 - ▶ Stroke symptom severity
 - ▶ Imaging criteria
 - ▶ Pre morbid functional status

- 
- ▶ Last Known Normal
 - ▶ Trials varied
 - ▶ 6h up to 12h
 - ▶ Ongoing studies to evaluate 12-24h
 - ▶ Longer time intervals → more dependent on imaging criteria
 - ▶ Age
 - ▶ Generally not an exclusion criteria by itself**
 - ▶ Stroke severity
 - ▶ NIHSS >2 as a minimum; most consider >6-8
 - ▶ Patient dependent

- 
- ▶ Pre morbid functional status
 - ▶ Most considered baseline independence to be a requisite
 - ▶ Patient specific
 - ▶ Imaging selection
 - ▶ Minimum: CT (-) and CTA
 - ▶ Large vessel occlusion (ICA, MCA – M1/M2)
 - ▶ ASPECTS >6-7
 - ▶ No hemorrhage
 - ▶ Advanced imaging
 - ▶ CT/MR perfusion
 - ▶ Multiphase CTA

Final thoughts

- ▶ Stroke is a treatable disease
- ▶ Advanced imaging, devices and care systems are markedly improving patient outcomes
 - ▶ And saving money
- ▶ Team approach is critical
 - ▶ Patient, transport/EMS, ED/Primary care provider, Stroke neurology, Imaging staff CT/MRI, Interventionalists, ICU/Stroke Unit, Rehabilitation
 - ▶ Nursing expertise critical at all points in pathway

Acute Stroke is the new STEMI

- ▶ Time sensitive disease process with treatments that work
- ▶ These patients do not wait
 - ▶ Appropriate and timely transfer to appropriate center
 - ▶ Rapid access to the necessary imaging studies
 - ▶ Rapid interpretation of studies and clinical assessments
- ▶ This is NOT a novel or experimental procedure
- ▶ Level 1 evidence
- ▶ Standard of care
- ▶ MT systems are evolving analogous to acute MI pathways 20y ago
